## Waves &amp; Boxes

# The Missing Link

## Part 1

*The relationship between time and price has a direct influence on trading profitability. Here's a look at how you can gain an insight by looking at the euro and the Romanian leu.*

**AS** traders progress along their learning curve, they begin to clearly observe the influence of the time/price relation in identifying the optimal trading setup. In spite of this, some traders — novices and experienced — always start the learning process with only price tools and their corresponding indicators, that is, classic technical analysis. Sooner or later, the successful trader will reach an advanced stage where learning the importance of time and its usefulness becomes a priority in the quest to further develop and acquire the much-sought-after professional trading techniques.

### THE EVOLUTION OF A TRADER

In the early stages of becoming a trader, we are all motivated to learn tons of techniques and indicators in order to perform the most profitable trades. We quickly observe that if the right approach isn't selected, we are in great danger of losing our trading capital.

Over time, I began to realize that studying and applying Elliott waves, Gann methodology, and mapping multiple time frames (top-down analysis) are a prelude to any final decision-making. Once this is done, the next step, which is the detailed study of the specific market you are trading, comes naturally. You can then identify the optimal time frame setup that works for you, one that consists of the most efficient elements of modern technical analysis.

### ESTABLISHING THE TRADING CONTEXT

Before I describe my time & price technique, I will briefly present and revisit some of the basic elements that contribute to its performance.

In spite of the so-called subjective labeling that many traders give to Elliott waves, I have been successfully using them for more than 20 years. Many traders misunderstand the usage of these waves mainly because of the lack of a probabilistic approach. Without probability, there wouldn't be a successful trading technique — classic *or* modern.

Your profitability is influenced and coordinated by the time & price relationship. You cannot label any type of pattern without first verifying several elements:

- Where is the market coming from?
- Where is the market going?
- What would be the most probable terminal key level of the current swing (trend) where time meets price?
- What is the most probable tendency, if any?
- If an existing sideways behavior is developing, what is its energy-restoring potential?
- If an existent trend is ongoing, where is the kinetic energy coming from? Can it be quantified?
- Is the market in a classic, extended, or failure mode, or on the contrary, is it in an embryonic state?
- What kind of technical tools can we use to get an optimal trading setup?

From an educational point of view, I will present two classic examples. In this first article of my series, I will discuss the euro vs. the Romanian leu (EUR/RON) in hindsight. In part 2, I will look at the gold continuous futures contract while it is developing in real time.

by Mircea Dologa

# Weekly chart Euro/RON spot forex

FIGURE 1: TIME AND PRICE RELATIONSHIP. Notice how W(4) retraced 33.3% of W(3) to the 4.0564 level.

The chart in Figure 1 illustrates the EUR/RON currency pair on the weekly time frame. I selected this example to establish a close-to-ideal relationship between time & price. I will focus the study on just the fourth wave, W(4).

As you can see in Figure 1, the area occupied by W(4) is mapped with the help of time & price parameters. With respect to price, W(4) retraced 33.3% of W(3) to the 4.0564 level. With respect to time, I have applied the *alternation principle*, which, from the classical point of view, states that the duration of W(4) is calculated based on the duration of W(2) wave, using the following formula:

$$\text{Time W(4)} = n \times \text{Time W(2)}$$

The  $n$  coefficient can take, more often than not, the following values: 1, 2, 3, 4... In this case, the value of  $n$  is 4.333. Very rarely is the value of  $n$  less than 1.0.

You should understand and be prepared for the alternation principle in your daily trading. The five-rule parameters pertain to the two corrective waves within an impulsive pattern: W(4) and W(2). Note that this principle implies that one valid element of the rules should be present. The alternation principle rules are:

- **Price:** Measure the distance, in price or in points, and compare the values of each corrective wave; oftentimes, W(2) retraces more than W(4).

- **Time:** Evaluate the duration of each corrective wave; count the corresponding bars on the time frame you are using. For example, more often than not, W(4) lasts longer than W(2) [ $n > 1$ ]. Very rarely is the duration of W(4) less than that of W(2) [ $n < 1$ ].

- **Severity:** Compare the Fibonacci price retracement ratios of the two waves. Typically, W(2) retraces farther than the W(4).

- **Intricacy:** Evaluate the number of subdivisions in both waves. Usually, W(4) will have more subdivisions than W(2).

- **Construction (wave structure):** Observe the degree of structural complexity (*mono/polywave*) of the wave. Usually, W(4) has a higher degree of complexity than W(2).

The chart in Figure 2 illustrates the same EUR/RON currency pair on the weekly time frame. As you can see from the chart, the span of W(4) wave is mapped by using the price retracement parameter [zero to 33.3% of W(3)].

On the time side, I applied the 28-bar multiplier, which is the duration of W(2), to forecast the duration of W(4). Thus, I calculated that W(4) will terminate after 121 corrective bars, which fully complies with the formula:

$$4.333 \times \text{W(2) duration}$$

The value of  $n = 4.333$  corresponds to one of the Charles Dow ratios, which are typically known as thirds, that is, 0.333, 0.666, 1.333, 1.666, 2.333, 2.666, and so on. The chart in Figure 2 illustrates an interesting observation between the relationship of

Identifying and labeling the most probable Elliott waves comes down to choosing the optimal time & price tools.

### Weekly chart Euro/RON spot forex

**FIGURE 2: PRICE RETRACEMENTS.** Here, the 28-bar multiplier, which is the duration of W(2), is used to forecast the duration of W(4).

W(4) and W(2) with respect to time — the terminations of most of the lower-degree waves of the double three W(4) complex wave (labeled W-X-Y) occur at a Fibonacci, Gann, or Charles Dow ratio threshold, within the duration of W(4).

All these observations were possible through the use of the alternation principle, that is, through the time formula with the specific multiplier. Thus, we can establish the following time ratios pertaining to the adequate subwaves of W(4):

- Subwave (a): W: W(4) consists of 14 bars, terminates at the 0.5 multiplier location, and corresponds to a Gann ratio, on the  $4.333 \times W(2)$  scale
- Subwave a: (b): W: W(4) consists of 14 bars, terminates at the 1.0 multiplier location, and corresponds to a Gann (Fibonacci) ratio on the  $4.333 \times W(2)$  scale
- Subwave b: (b): W: W(4) has 14 bars, terminates at the 1.0 multiplier location, corresponds to a Gann (Fibonacci) ratio on the  $4.333 \times W(2)$  scale
- Subwave c: (b): W: W(4) has 13 bars, terminates at the 1.5 multiplier location, and corresponds to a Gann ratio [error margin is (+ 1) bar] on the  $4.333 \times W(2)$  scale
- Subwave (c): W: W(4) has 21 bars [(0.50 + 0.25) or 0.75 of 28 bars], terminates at the 2.25 multiplier location, and corresponds to a Gann ratio on the  $4.333 \times W(2)$  scale
- Subwave X: W(4) has 14 bars [(2.75 – 2.25) or 0.5 of 28 bars], terminates at the 2.75 multiplier location, and corresponds to a Gann ratio [error margin is (+ 1) bar] on the  $4.333 \times W(2)$  scale

- Subwave (a): Y: W(4) has seven bars [(3.00 – 2.75) or 0.25 of 28 bars], terminates at the 3.0 multiplier location, and corresponds to a Gann (Fibonacci) ratio, on the  $4.333 \times W(2)$  scale
- Subwave (b): Y: W(4) has nine bars [(3.333 – 3.00) or 0.333 of 28 bars], terminates at the 3.333 multiplier location, and corresponds to a Charles Dow ratio [error margin is (+ 1) bar], on the  $4.333 \times W(2)$  scale
- Subwave (c): Y: W(4) has 28 bars [(4.333 – 3.333) or 1.0 of 28 bars], terminates at the 4.333 multiplier terminal location, and corresponds to a Charles Dow ratio, on the  $4.333 \times W(2)$  scale.

**FIGURE 3: ELLIOTT WAVE SETUP.** Most reversals take place at the time & price confluences. Identifying and labeling the most probable Elliott waves is a matter of choosing the optimal time & price tools.

Figure 3 completes the Elliott W(4) wave setup by adding some interesting information. Here are my observations and interpretations of the price chart and the oscillator in the subchart.

- The Elliott subwave count of W(4) with its three wave subdivisions, a: (a) to W: W(4)
- The time relation of W(4) to W(2), which reveals the terminal levels of most of the lower-degree waves of the double three W(4) complex wave (labeled W-X-Y)
- The W(4)/W(1) overlapping border line is located at the 3.8382 key level. It is important to continuously monitor the distance between price and this overlapping border line. It reveals important information regarding the potential development of W(4) wave, which could unveil the future development of W(5), the terminal wave, and implicitly the termination of the ascending impulsive pattern. The bigger the W(4) retracement, the weaker the W(5) wave will be in its development.
- The time relationship within the W(4) wave, considered to be equal to a ratio of 1.0 but containing 121 bars, in hindsight, reveals the terminal levels of most of the lower-degree waves of the double three W(4) complex wave (W-X-Y) and the multiple time clusters. Thus, the following time ratios pertain to the W(4) wave:
  - Subwave (a): W: W(4) has 14 bars, terminates at the 0.125 multiplier location, and corresponds to a Gann ratio [error margin is (-1) bar], on the 121 bar scale.
  - Subwave a: (b): W: W(4) has 14 bars, terminates at the 0.236 multiplier location, and corresponds to a Fibonacci ratio, on the 121 bar scale.
  - Subwave b: (b): W: W(4) has 14 bars, terminates at the 0.236 multiplier location, and corresponds to a Fibonacci ratio, on the 121 bar scale
  - Subwave c: (b): W: W(4) has 13 bars, terminates at the 0.33 multiplier location, and corresponds to a Charles Dow ratio [error margin is (-2) bars], on the 121 bar scale
  - Subwave (c): W: W(4) has 21 bars, terminates at the 0.50 multiplier location, and corresponds to a Gann ratio [error margin is (-2) bars], on the 121 bar scale
  - Subwave X: W(4) has 14 bars, terminates at the 0.66 multiplier location, and corresponds to a Charles Dow ratio [error margin is (+2) bars], on the 121 bar scale
  - Subwave (b): Y: W(4) has nine bars, terminates at the 0.764 multiplier location, and corresponds to a Fibonacci ratio, on the 121 bar scale
  - Subwave (c): Y: W(4) has 28 bars, terminates at the 1.0 multiplier terminal location, and corresponds to a Gann (Fibonacci) ratio, on the 121 bar scale.
- The **time clusters** within W(4), observed in hindsight, between the ratio locations of 4.333 x W(2) scale and the 121-bar scale, were developed in almost every W(4) sub-wave termination:
  - Time cluster n° 1 at the termination of (a): W: W(4),
  - Time cluster n° 2 at the termination of a: (b): W: W(4),
  - Time cluster n° 3 at the termination of (b): W: W(4),
  - Time cluster n° 4 at the termination of (c): W: W(4),

**FIGURE 5: TURNING POINTS.** Most of the reversals take place at the time & price confluences governed by Gann boxes or by the 45-degree geometric angle.

thus revealing the strength of the market, by staying above the 33.33% threshold of the W(4) wave space.

The shallow 4x1 angle is of lesser importance on this specific timeframe. Instead, the angle illustrated by the TL-1/3 trendline — created by joining the termination of W(3) and W(4) — becomes the diagonal of the rectangular space of W(4) wave. It plays an important role here, since it becomes a symmetry axis within the development zone of W(4) wave.

The Gann box does a good job of revealing the degree of freedom of W(4) wave, in hindsight. But how can this be studied in real time, while the market is fluctuating in a chaotic manner within the rectangular space?

To answer this question, I have used a Gann box and its multiples, out of the first swing of the W(4) wave associated with the use of the 45-degree geometric angle. The Gann boxes (especially the 144) with the 45-degree angles, both drawn by hand on millimeter paper, are the specialty of Dawn Bolton-Smith, the matriarch of technical analysis and a life member of the Australian Technical Analysts Association (ATAA in Sydney), who, in spite of being in her 80s, is still doing her

daily market analysis.

The first Gann box in Figure 5 uses a diagonal size and angle value that is equal to the trendline of W(4)'s first subwave swing. Its angle value coincides with that of the 45-degree geometric angle. I then multiplied this Gann box size to better describe the market flow. I associated it with the drawings of the parallel 45-degree geometric angles originating at an extreme pivot high or a low. These boxes harmonically govern the entire area occupied by W(4). Moreover, every time there is a change in trend, the 45-degree angles act as a guide. The entire W(4) wave terminates at the eighth drawn Gann box with the following inner coordinates: 0.25 of price, and 0.666 of time.

### FINDING THE TURNING POINTS

Most of the reversals in Figures 4 and 5 take place at the time & price confluences governed by the Gann boxes or by the 45-degree geometric angle. The time & price relationship practiced in real time, with its array of boxes drawn using the first swing, illustrates its efficiency in revealing a market turn. Once again, you see the importance of using a systematic approach, which consists of strictly monitoring the developing process of the confluences. Once again, if a box or an angle is overcome, just draw and consider the next one.

Take the time to understand the relationship between time & price and the likelihood of price meeting confluence points. In the second part of this article series, I will show you how the time & price relationship can be seen developing in real time.

**Gann's main credo regarding the time & price relationship plays a big role in identifying market turns.**
